Customize bridging

How to: Configure transfer speed and maximum cost

Copy page

Set a transfer speed and maximum fee to balance performance and cost

By default, App Kit uses CCTP's **Fast Transfer** feature to optimize for speed. However, **this can incur higher fees**. If performance is not a concern, you can specify a slow transfer speed, which uses CCTP's Standard Transfer feature.

To balance performance and cost, you can set the maximum fee you want to pay on fast bridge transfers. The transfer switches to slow if the cost is above your limit.

Prerequisites

Before you begin, ensure that you've:

- **Installed App Kit**
- **Configured an adapter**

These are required so any example below runs with a valid `kit` and `adapter`.

Configure slow speed

This code configures a slow transfer speed:

TypeScript

```typescript
// Slow transfer speed
const result = await kit.bridge({
  from: { adapter, chain: "Ethereum_Sepolia" },
  to: { adapter, chain: "Arc_Testnet" },
  amount: "1.00",
  config: { transferSpeed: "SLOW" }, // Slow transfer speed
});
```

Configure maximum fee

Set the maximum fee that you want to pay for the CCTP fast burn.

This code configures a maximum fee of 0.10 USDC:

TypeScript

```typescript
const result = await kit.bridge({
  from: { adapter, chain: "Ethereum_Sepolia" },
  to: {
    adapter,
    chain: "Arc_Testnet",
  },
  amount: "1.00",
  config: {
    transferSpeed: "FAST", // Fast transfer speed (can be omitted)
    maxFee: "0.10", // Max 0.10 USDC fee
  },
});
```
