Customize bridging

How to: Use the CCTP forwarding service

Copy page

Use the CCTP Forwarding Service on bridge transfers

You can use the **CCTP Forwarding Service** on bridge transfers. When enabled, it fetches the attestation and submits the mint on the destination chain. You don't need to poll for attestations or have access to a wallet on the destination chain.

Prerequisites

Before you begin, ensure that you've:

- **Installed App Kit**
- **Configured an adapter**

These are required so any example below runs with a valid `kit` and `adapter`.

Use with adapters on both chains

Set `useForwarder: true` when you have adapters for both chains but want the Forwarding Service to submit the mint transaction on the destination:

TypeScript

```
const result = await kit.bridge({
  from: { adapter, chain: "Ethereum_Sepolia" },
  to: {
    adapter,
    chain: "Arc_Testnet",
    useForwarder: true,
  },
  amount: "1.00",
});
```

Use without a destination adapter

When you don't have access to a wallet on the destination chain, such as with server-side or custodial bridge flows, omit the destination adapter and pass `recipientAddress` with `useForwarder: true` :

TypeScript

```
const result = await kit.bridge({
  from: { adapter, chain: "Ethereum_Sepolia" },
  to: {
    recipientAddress: "RECIPIENT_ADDRESS",
    chain: "Arc_Testnet",
    useForwarder: true,
  },
  amount: "1.00",
});
```

In this mode, mint confirmation comes from the Circle Iris API response rather than an onchain receipt. Because the Forwarding Service submits the mint transaction, no locally signed transaction hash is returned and the mint step's `data` field is `undefined` .

Forwarding fee

The Forwarding Service charges a **fee** that is deducted from the amount minted on the destination chain. When you **estimate costs** for a bridge transfer, the result includes the

forwarding fee. See **How Bridge Fees Work** for details.
